ACKNOWLEDGEMENTS

The National Trauma Database Committee would like to thank all those who have participated and contributed to our second report from January to December 2007.

We would like to especially thank the following:

1. All centre coordinators, doctors, medical assistants and staff nurses from the Emergency Departments and Surgery/Neurosurgery Departments of the participating hospitals. Without their commitment, hard work, timely data collection and submission, this report would not be possible.
2. The Clinical Research Centre for its technical support, especially Dr Lim Teck Onn and Dr Jamaiah Haniff for their continuous support and guidance.
3. The Ministry of Health, Malaysia for the research grants to set up the registry.

INTRODUCTION

The purpose of this report is to provide a descriptive analysis of patients hospitalised with major trauma in participating Ministry of Health (MOH) hospitals in Malaysia for 2007. The data source for this report is the National Trauma Database (NTrD). Major trauma cases were selected based on the following criteria:

- i. Patients who died from injuries after admission.
- ii. Patients with Injury Severity Score (ISS) of > 15.
- iii. Patients admitted to Intensive care Units (ICU) or High Dependency Wards (HDW) for > 24 hours and mechanically ventilated.
- iv. Urgent surgery within 24 hours for intracranial, intra-thoracic, intra-abdominal, or fixation for pelvic or spinal injuries.
- v. All severe head injury patients rated 3-8 on the Glasgow Coma Scale (GCS)
- vi. All moderate head injury patients rated 9-12 on the GCS.

The National Trauma Database 2007 – Second Report provides information about the profile of persons with major trauma who were admitted to participating hospitals throughout Malaysia.

The report is presented in Five Chapters:

Chapter 1 provides an overview on the demographics of the patients, including gender, age group, race, admission time, admission day, and admission type.

Chapter 2 examines the injury details of the patients, such as injury mechanisms, injury intent, injury causes, injury places, medical reviewers, disposition, ICU admission, and systolic BP. The patients were also rated on the Glasgow Coma Scale (GCS), Revised Trauma Score (RTS), Abbreviated Injury Scale (AIS) and Injury Severity Score (ISS). Data on Traumatic Brain Injuries including, number, type and percentages, are also presented.

Chapter 3 describes the operative management carried out on patients including the management of operations and procedures.

Chapter 4 provides information about the outcome of the patients, which is then categorised according to age groups, injury mechanisms, injury causes, injury places, admission types, systolic BP, GCS, RTS, AIS, ISS, and ICU admission. The probability of survival is also measured using the Trauma Score-Injury Severity Score (TRISS) methodology which includes the RTS, ISS, mechanism of injuries and patient's age.

Chapter 5 includes the total length of stay in hospital and ICU.

The limitations of the study are:

- i. Under reporting - The data reported comes from less than the actual number of cases.

- ii. Missing data - Missing values not included in the analysis makes the sample size for some of the time periods shorter than others.

Hopefully the information in this report will be used to implement strategies to strengthen and improve trauma care in the country.

About NTrD

The National Trauma Database (NTrD) is a service initiated and supported by the Ministry of Health (MOH) to collect information about trauma incidence in Malaysia, and to evaluate its risk factors and treatment in the country. Such information will be of use to the MOH, Non-Governmental Organisations, private healthcare providers and the other interested parties in programme planning and evaluation, leading to trauma prevention and control.

The NTrD is co-sponsored by the following organisations of the Ministry of Health Malaysia:

- i. Emergency Medical and Trauma Services
- ii. Neurosurgery Services
- iii. Surgery Services
- iv. Clinical Research Centre

The objectives of the NTrD are to:

1. To determine the frequency, mechanism of injuries and distribution of major trauma in Malaysia. The statistics and data will be of importance in determining precisely the private and public resources utilised in its management.
2. To determine the outcome and probability of survival of trauma patients.
3. To evaluate major trauma management practices in the participating hospitals and to come up with guidelines for improved trauma care.
4. To determine the effectiveness and impact of the introduction of improved practices.
5. To stimulate and facilitate research on major trauma and its management.

The key data sources identified for this database are:

- All Emergency Physicians and Neurosurgeons in Malaysia beginning with those currently working in the MOH, and later extending to those beyond MOH (private, universities and Armed Forces) for data on Major Trauma and Head Injury patients in the country.

METHOD OF DATA COLLECTION

Coverage

In 2007 there were five MOH hospitals. The number of participating centres is the same as with the previous report involving the May 2006 to April 2007 cases.

Registration method

One Notification Form, called the Case Report Form (CRF), is employed in data collection (Refer to Appendix A). The CRF gathers information on patient demography, admission, injury details, clinical details, diagnostic and operative procedures, in-hospital outcome and Injury Severity Scores. The CRFs are used as part of the clinical record. The completed forms are sent to NTrD where the data is analysed, interpreted and presented in regular reports and disseminated to the users. The participation of Source Data Providers (SDPs) is entirely voluntary.

The data transferred to NTrD is kept strictly confidential with access only to authorised individuals working in the NTrD.

Statistical analysis

This report is a descriptive analysis. All data is described in terms of percentages except continuous data like length of stay (LOS). Missing data was ignored and the analysis confined to available data. The TRISS methodology is used for the probability of survival which incorporate ISS, RTS, mechanism of injury and the patient's age.

MEMBERS OF THE STEERING COMMITTEE OF THE NTrD

1.	Dr Lim Teck Onn (Chairman)	Clinical Research Centre, Ministry of Health
2.	Dr Sabariah Faizah Bte Jamaluddin (Co-Chairman)	Head of Department Emergency Department, Hospital Sungai Buloh

TRISS	Trauma-Score Injury Severity Score

GLOSSARY

Disease Register	The ongoing systemic collection, analysis and interpretation of specific disease data essential to the planning, implementation and evaluation of clinical and public health practice, closely integrated with dissemination of these data to those who need to know. The final link in the chain is the application of these data to the management, prevention and control of the disease. A registration system includes a functional capacity for data collection, analysis and dissemination linked to clinical and public health programmes.
Site	The location of an SDP reporting data on registrable patients to the registry.
Source Data Providers	The individuals or institutions that report the required data to the registry.
Sponsor	The individuals or institutions that own the registry.
Expert Panel	Individuals who are subject matter experts i.e. Emergency Physicians and Neurosurgeons. The expert group will keep abreast of the latest development in this area. They should be convened to decide on the initial data collection process, develop the Performa and data content as well as a guide for future development. They ensure that the database have a sound technical as well as scientific basis.

REPORT SUMMARY

This second report is based on 584 major trauma cases reported to NTrD by five hospitals in 2007. In the event of a patient being transferred from one centre to another, he would be counted as two records/cases, one for each centre.

1 DEMOGRAPHICS

There were a total of 114,032 trauma patients admitted to the Emergency Departments(ED) in 2007 in the five centres. Centre B had the highest number with 51,621 patients. Major trauma patients constituted 0.5% of all trauma admissions. Centre B reported the highest number of major trauma cases with 49.4%.

Male patients made up the majority of trauma patients (84.6%). Most of the major trauma patients were young - within the age group of 15-24 (34.5%) and 25-34 (21.3%). Malays accounted for 51.8% of cases while 11% were foreigners.

Most major trauma patients were admitted in the evenings and late nights, between 1801–2400hrs (29.8%) and 0001 – 0600hrs (29.5%). Wednesdays were the busiest days for major trauma cases, making up 15.9% of admissions, followed by Sundays with 15.6%.

More than half (54.5%) of the major trauma cases were referred from other medical facilities with Centre B recording the highest transferred cases (68.1%) while most cases of Centre A were from direct admission. Most of the referred cases were from other hospitals with specialists.

2 INJURY DETAILS

Blunt injuries made up 91.5% of the cases with the majority being unintentional (77.2%). Road/street and highway trauma accounted for 76% of cases with motorcyclists the most commonly injured.

Most major trauma patients were reviewed initially by the medical officer or trainees while only 3% and 8.4% were reviewed by the emergency physician and surgeon respectively. 30.3% of the major trauma patients were sent directly to the General Ward from ED and 17.1% were sent to the operating theatre (OT). During their stay in hospital only 32.2% patients received ICU care. In Centre B, 90% of patients were nursed in the ward only.

More than half (63.3%) had a systolic BP greater than 120mmHg on admission to ED and only 6% had systolic BP of less than 90mmHg. Patients with an initial Glasgow Coma Scale (GCS) of 3-8 accounted for 55.6% of all major trauma cases with Centre E recording 81% of its cases with similar GCS. Of patients with moderate head injuries, (GCS 9-12), 18.4% of cases were not classified as major trauma. Intracranial injuries accounted for 45% of all traumatic brain injuries with traumatic subdural haemorrhages the most common at 28.3%.

Ninety percent of major trauma patients had injuries to the head and neck followed by the extremities or pelvic girdle (19.7%). The majority of injuries with AIS of ≥ 3 involved the head and neck (85%).

More than half of the patients (68.7%) had an Injury Severity Score (ISS) between 16-25. Even though 18.8% had an ISS of less than 10, these patients met other criteria for inclusion as major trauma cases

3 OPERATION MANAGEMENT

184 (48.29%) major trauma cases underwent operations with the most common being intracranial surgery (74.74%) with 23.15% for decompressive craniectomy.

4 OUTCOME

The overall mortality in all the participating centres for major trauma was 28.6% and ranged from 23.1% to 38.3%.

Fifty-two percent of survivors were discharged home and 28.6% were transferred to other hospitals for continued care. 9.5% survivors were discharged against medical advice. The majority of survivors were between the ages of 0 to 44 years, while the percentage of deaths were 31.0% to 58.3% for cases between the ages of 45 to 84 years. Survivors from blunt injuries and penetrations were 72.21% and 61.11% respectively.

The majority of major trauma cases were due to road traffic accidents (70.1%), followed by falls from heights (8.3%), assaults (5.2%) and industrial accidents (1.6%). 39.3% of patients who were injured at home died, followed by those injured at industrial/construction sites (37.5%) and road/highway injuries at 27.6%.

The highest percentage of survivors were back seat passengers (83.3%), while pedestrians recorded the highest percentage of deaths at 39.4%, followed by bicyclists (36.3%), motorcycle pillion riders (34.8%) and motorcycle riders (24.1%).

Of the patients who were transferred, 76.5% survived. There was a higher death rate in patients who were admitted directly (33.7%) compared to those who were transferred (24.5%).

Victims who had systolic blood pressure more than 76mmHg at admission to the hospitals had equal or highest percentage of survivals (50-71.32%) compared to deaths. Patients with Glasgow Coma Scale (GCS) ratings of 13-15 and 9-12 had the highest survival percentages at 93.24% and 82.22% respectively. On the other hand, victims with GCS ratings of 3-8 had a survival percentage of 59.82%. Victims with RTS > 5.0 had a survival rate of more than 68.0%, while 74.8% of patients with AIS > 3 survived. Patients with ISS of > 40 had a 50% death rate, which rose to 70% for those not admitted to ICU.

Following TRISS calculations (which determines the probability of survival (Ps) of a patient from the ISS and RTS), 68.6% of major trauma patients were expected to survive ($Ps \geq 0.5$) compared to the actual observed survival rate of 71.4%. Of the 89.4% patients

expected to survive from the major trauma cases, only 75.2% of them made it. Forty-five percent of patients expected to die, actually survived.

5 LENGTH OF STAY

The average length of stay (ALOS) for all the five centres ranged from five to 12 days and 52% were discharged home. Centre A and B recorded ALOS of less than six days while the other three centres recorded ALOS between 11 and 12 days.

Patients who survived had a longer ALOS of between 5-15 days compared to non-survivors (3-7 days). The ALOS for those admitted in ICU and survived were between four to eight days. However, those who died after admission to ICU obviously had a shorter ALOS - between 0-5 days.

In term of type of admission and their ALOS, those who were presented directly to the hospitals had a shorter ALOS of eight days compared to those who transferred from other facilities with an ALOS of 10.

Injuries associated with the longest ALOS were road traffic accidents and burns at nine days. This was followed by injuries from assaults at seven days. Industrial accidents, stabbings and falls from less than two metres in height were next with ALOS of five days. Surprisingly falls from more than two metres had a shorter ALOS of three days. Data was not available for the cause of injuries to those who stayed longest with ALOS of 14 days.
