²University Malaya Medical Centre

Summary

1. The in-hospital mortality rates of ACS patients remained consistent at seven to eight percent over the 3-year period from 2006 to 2008.
2. The in-hospital mortalities rates for STEMI and NSTEMI (7-8%) were higher compared to rates in the GRACE 2¹ (6.2%) registry during the same period.
3. From 2006 to 2008, statistical significant factors of in-hospital death in STEMI were higher Killip class, higher TIMI risk score and pre-morbid diabetes mellitus. For NSTEMI/UA, the statistical significant factors were higher Killip class and heart failure.

In-hospital and 30-day outcome

All three years had similar in-hospital and 30-day mortalities rates for the entire ACS cohort. For in-hospital mortality, the rates were between 7 and 8% while for 30 days mortality, it was between 15 and 24%. [Table 5.1] The in-hospital mortality was highest in STEMI (9-10%), slightly lower in NSTEMI (7-10%), and lowest in UA (2-4%). In contrast, the 30-day mortality of NSTEMI was slightly higher compared to STEMI (19-29% and 15-21% respectively). [Table 5.8]

The mortality rates of our patients were higher than the rates in several global and regional ACS registries within the same period. The expanded Global Registry of Acute Coronary Events (GRACE2)¹ from 2001 to 2007 reported in-hospital mortality rates of 6.2% in STEMI, 2.9% in NSTEMI and 1.7% in unstable angina patients¹. The Gulf Registry of Acute Coronary Events (Gulf RACE) conducted in 2006 reported in-hospital mortality of just 3% for the entire registry cohort².

Outcome by patient characteristics

The mortality rates according to the patients' demographics and pre-morbid medical conditions in 2007 and 2008 were similar to those noted in 2006. Specifically, higher mortality rates were observed in the elderly, female patients and patients with pre-morbid diabetes mellitus. [Table 5.2, 5.3 & 5.4]

Outcome of STEMI by treatment

Patients who received fibrinolytic therapy had lower in-hospital and 30-day mortality rates compared to those who were not on this therapy. This observation was consistent throughout the 3-year period. [Table 5.9.1]

In STEMI, the percentage of patients who had PCI and CABG at admission were similar in all three years. Mortality rates in patients who had PCI were slightly lower compared to those who did not have PCI. [Table 5.9.2] Although steady increases in mortality rates were noted

in patients who had CABG (0-38% for both in-hospital and 30-day mortality), the absolute numbers of the surgeries and deaths were extremely small. [Table 5.9.3]

Outcome of NSTEMI/UA by treatment

In NSTEMI and UA, patients who had PCI at admission appeared to have lower in-hospital mortality rates compared to those who did not have PCI. At 30 days, the survival benefit associated with PCI was even more obvious. [Table 5.10.1] The absolute number of patients who underwent CABG was very small. [Table 5.10.2]

Prognostic factors

From 2006 to 2008, statistical significant associations of in-hospital death in STEMI were higher Killip class, higher TIMI risk score and pre-morbid diabetes mellitus. The other associated factors with an increased risk of in-hospital death were fibrinolytic therapy, former or current cigarette smoking, family history of premature cardiovascular disease, dyslipidaemia, and hypertension. [Table 5.11.1-5.11.3 & Table 5.13.1-5.13.3]

For in-hospital mortality among NSTEMI/UA, the statistical significant associations were higher Killip class and history of heart failure. The other associated factors include former or current cigarette smoking, diabetes mellitus and higher TIMI risk score. [Table 5.12.1-5.12.3 & Table 5.14.1-5.14.3]
